
Peter Stratton, Emma Silver, Natasha Nascimento, Gwen Powell, Liz McDonnell and Ewa Novotny.

These tables present the result of a systematic collation of empirical studies of outcomes over 10 years of English language publication in refereed journals.

The Review is intended to be a resource for practitioners and researchers, as a readily available source of recent research publications on specific conditions. For this purpose a description of the main aspects of each study has been provided in a standard form. A full alphabetical listing of references is provided from page 98. A substantial further study, primarily by Emma Silver and Natasha Nascimento, involves a detailed coding of each article so that we can report trends and patterns in the research. This project is currently being written up for journal submission. An account of the methodology will be provided in that publication.

In summary: The listing does not include review articles that did not report original data. We have taken a broad definition of family, couple and systemic therapy, and most of the articles were identified by searching electronic data-bases with a variety of keywords, then reviewing every publication to select those that fitted our criteria.

In an enterprise as substantial and complex as this one, there will inevitably be errors and omissions. Please do check the sections where you are familiar with the research literature and email Peter with suggestions for improvement. P.m.stratton@ntlworld.com

How to use the Tables

The 220 studies are grouped according to the client issue identified in the research and whether the referred person was an adult or child. To move to a particular Table, click on the Table of Contents then Ctrl-Click on the title of that table.

To move to the reference for an article, either go to the alphabetical list of references or use Search (Ctrl-F) and enter the name of the first author. If you put ^p in front of the author’s name (e.g. ^pliddle) you will be taken only to the articles on which the researcher was first author.

Acknowledgements: We are extremely grateful for the support of the Board and Executive of the Association for Family Therapy for providing a research grant to support the work throughout the lengthy process of collating the review. Also for support by UKCP during 2009 and 2010. We are grateful to many colleagues who suggested articles that we might otherwise have missed.

| 1.1   | RCT evaluating the effectiveness of solution-focused therapy (SFT) vs. short-term psychodynamic psychotherapy (ST) vs. long-term psychodynamic psychotherapy (LT) in outpatients with depression or anxiety | SFT (n=97) Mean age 33.6 years (SD 7.2) 25.8% male  
ST (n=101) Mean age 32.1 years (SD 7) 25.7% male  
LT (n=128) Mean age 31.6 years (SD 6.6) 21.1% male | Measures for research subjects:  
Work Ability Index  
Work subscale (SAS-Work) of the Social Adjustment Scale  
Perceived Psychological Functioning Scale | 1 year  
2 years  
3 years | • At 3-year follow-up, statistically significant improvement on WAI, SAS-Work and Perceived Psychological Functioning Scale  
• The short-term therapies showed 4–11% more improved work ability scores than long-term therapy at the 7 month follow-up  
• No significant differences between therapies at 2-year follow-up  
• After 3 years of follow-up, LT more effective than SFT and ST |
| 1.2   | RCT examining the effectiveness of solution-focused therapy (SFT) vs. long-term psychodynamic psychotherapy (LT) vs. short-term psychodynamic psychotherapy (ST) in the treatment of mood and anxiety disorders | SFT (n = 97) Mean age 33.6 years (SD 7.2) 25.8% male  
ST (n = 101) Mean age 32.1 years (SD 7) 25.7% male  
LT (n = 128) Mean age 31.6 years (SD 6.6) 21.1% male | Measures for research subjects:  
Depressive symptoms measures by Beck Depression Inventory (BDI) and Hamilton Depression Rating Scale (HAMD)  
Anxiety symptoms measured by Symptom Check List Anxiety Scale (SCL-90-Anx) and Hamilton Anxiety Rating Scale (HAMA) | 3 years | • A statistically significant reduction of symptoms on BDI, HAMD, SCL-90-Anx and HAMA at follow-up  
• ST more effective than LT at 1st year on the four outcome measures, but no significant differences at 2 years  
• At 3 years, LT was more effective  
• No statistically significant differences for effectiveness of short term therapies |
| 1.3 | Lemmens, Eisler et al. (2008) Belgium | RCT examining the effectiveness of treatment as usual (TAU) vs. TAU plus single family therapy (SFT) vs. TAU plus multi-family group therapy (MFT) in the treatment of severely depressed inpatients | 83 patients recruited  
- MFT ($n = 35$)  
  Mean age 43.9 years (SD 8.3)  
  80% female  
- SFT ($n = 23$)  
  Mean age 40.2 years (SD 9.1)  
  64% female  
- TAU ($n = 25$)  
  Mean age 43.2 years (SD 8.4)  
  69.6% female | Response to treatment – changes on the Beck Depression Inventory | 15 months | • Multi-family group and single family therapy conditions showed significantly higher rates of treatment responders (49%, 24% and 9% respectively), and higher rates of patients no longer using antidepressant medication (26%, 16% and 0% respectively) compared to the treatment as usual condition at 15 months  
• Partners taking part in the family treatments were significantly more likely to notice the improvements in the emotional health of the patient early on compared to those in the treatment as usual condition |

| 1.4 | Beardslee, Wright et al. (2007) USA | RCT evaluating long term effects from two standardized, manual-based prevention strategies for families with parental mood disorder. See Beardslee, Gladstone et al. (2003) for details of interventions | 105 families | Behavioural functioning  
Parental and child psychopathology  
Response to intervention  
Parental global functioning  
Child internalizing symptomatology  
See Beardslee, Gladstone et al. (2003) for details of outcome measures | Every 9 to 12 months after recruitment to study | • Both interventions produced sustained effects  
• Clinician-based families had significantly more gains in parental child-related behaviours and attitudes and in child-reported understanding of parental disorder  
• Child and parent family functioning increased for both groups and internalizing symptoms decreased for both groups |

females

### COCT

- Mean age 44.95
- Mean age of partner 65%
females

### Depressed symptoms from pre test at 24.75 (SD 6.03) to post treatment at 15.55 (SD 11.58).

- CBT at 26.05 (SD 8.18) at pre tests and 14.50 (SD 10.04) at post test.

- 50% of depressed patients showed recovery after undergoing CBT, IPT or COCT.

- No significantly better improvements in relationship functioning with COCT therapy when compared to CBT and IPT.

- COCT significant positive effects of the COCT were found with regard to Emotion Expression (EE).
| 4.2 | Miklowitz, Otto et al. (2007) USA | RCT examining efficacy of three intensive psychotherapies (family-focused therapy (FFT); interpersonal and social rhythm therapy (IPSRT); cognitive behaviour therapy (CBT)) compared to a control group (collaborative care; CC) for patients with bipolar depression | FFT; n = 26 IPSRT; n = 62 CBT; n = 75 CC; n = 130 Total participants: Mean age 40.13 years (SD 11.77) 59% female | Time to recovery Proportion of patients classified in each of the 12 study months Montgomery-Asberg Depression Rating Scale Young Mania Rating Scale | 12 months | • No difference in attrition rates between intensive psychotherapy and collaborative care • Significantly higher year end recovery rates and shorter times to recovery in intensive psychotherapy group compared to CC • Patients in intensive psychotherapy group were 1.58 times more likely to be clinically well during any study month compared to CC • No statistically significant differences seen in the outcomes of FFT, IPSRT and CBT |
| 4.3 | Miller, Solomon et al. (2004) USA | RCT evaluating the effectiveness of family therapy as an adjunctive treatment to pharmacotherapy in helping patients recover from mood episodes of bipolar I disorder. | 92 patients meeting criteria for bipolar I disorder randomly assigned to the following groups: Family therapy plus pharmacotherapy (n = 33) Mean age 40 years (SD 10) Multifamily psychoeducational group therapy plus pharmacotherapy (n = 30) Mean age 39 years (SD 12) 40% male | Main outcome – time to recovery Modified Hamilton Rating Scale for Depression Bech–Rafaelsen Mania Scale | Monthly assessments after intake into trial | Time to recovery did not differ between the groups |
| 4.4 | Miklowitz, George et al. (2003) USA | RCT evaluating whether combining family-focused therapy (FFT) with pharmacotherapy vs. crisis management intervention (CM) during a post-episode interval enhances patients’ mood stability during maintenance treatment in bipolar patients | **Pharmacotherapy alone**  
(n = 29)  
Mean age 39 years (SD 13)  
34% male | **FFT** (n = 31)  
Mean age 35.7 years (SD 9.2)  
58% female | **CM** (n = 70)  
Mean age 35.6 years (SD 10.6)  
66% female | Primary outcome measure - Schedule for Affective Disorders and Schizophrenia, Change Version  
Maintenance Treatment Scales - intensity of patients’ drug regimens  
Compliance with medication regimen  
Relapse symptoms  
Medication adherence | 3, 6, and 9 months after study entry  
(covers the period of active psychosocial treatment) and at 12, 18, and 24 months  
(covers the post-treatment interval) | • Patients undergoing FFT had fewer relapses than patients undergoing CM  
• Patients undergoing FFT showed greater reductions in mood disorder symptoms and better medication adherence during the 2 years than patients undergoing CM |

| 4.5 | Rea, Tompson et al. (2003) USA | RCT evaluating manual-based, family-focused psychoeducational therapy (FFT) vs. individually focused patient treatment (IPM) for recently hospitalised bipolar, manic patients (DSM-III-R). Both treatments were combined with concurrent treatment with mood stabilising medications. | **FFT** (n = 53)  
Mean age 25.6 years (SD 6.86)  
46% male | **Control** (n = 25)  
Mean age 24.6 years (SD 5.8)  
40% male | Symptomatic functioning  
Rehospitalisation  
Medication compliance  
Brief Psychiatric Rating Scale  
Schedule for Affective Disorders and Schizophrenia—Change Version | 12 months post-treatment | Compared with patients in individual therapy, those in family-focused treatment were less likely to be rehospitalized during the 2-year study period. Patients in family treatment also experienced fewer mood disorder relapses over the 2 years, although they did not differ from patients in individual treatment in their likelihood of a first relapse |
<p>| 4.6 | Miklowitz, Simoneau et al. (2000) | RCT examining the efficacy of a 9-month family-focused psychoeducational treatment (FFT) vs. comparison treatment (two family education sessions and follow-up crisis management; CM) in 101 bipolar patients | FFT ($n = 31$) CM ($n = 70$) | Expressed Emotion Symptomatic outcome and medication compliance - Schedule for Affective Disorders and Schizophrenia, change version | 12 months | • Patients assigned to FFT had fewer relapses and longer delays before relapses, compared to CM group • FFT group showed greater improvements in depressive (but not manic) symptoms |
| 4.7 | Ozerdem, Oguz et al. (2009) | A case series based study evaluating the applicability of Family-focused Therapy (FFT) in a non-Western culture for patients with bipolar disorder and their family members. | $n = 10$ Mean age = 25.50 (SD 8.07) 50% females | Global Assessment of Functioning (GAF) scale Clinical Global Impression (CGI) | Mean follow up 54.44 weeks (+/-24.96 weeks) | • Preliminary analysis indicates that FFT can be successfully applied in non-Western cultures. • Frequency of episodes significantly decreased from pre-treatment mean of 1.66 to a post-treatment mean of 0.55. • Noted positive improvement on Global Assessment of Functioning Scores and Clinical Global Impression Scale • Treatment appeared to have a positive effect on families’ communication skills. |
| 4.8 | Solomon, Gabor et al. (2008) | RCT study examining the efficacy of three treatments for preventing recurrence of bipolar mood episodes and hospitalizations: (1) individual family therapy plus pharmacotherapy vs (2) multifamily group therapy plus pharmacotherapy vs (3) pharmacotherapy alone. | $n = 53$ Mean age 41 years (SD 13) 57% female Individual family therapy plus pharmacotherapy ($n = 16$) Multifamily group therapy plus pharmacotherapy ($n = 21$) Pharmacotherapy alone ($n = 16$) | Modified Hamilton Rating Scale for Depression–17-item Bech - Rafaelsen Mania Scale Global Assessment of Functioning (GAF) | | • There were no significant differences between the three treatment groups. Therefore, neither multifamily therapy nor individual therapy was more effective than standard pharmacotherapy. • However, there are potential benefits of multifamily therapy: the frequency of hospitalisation was only 5% for the participants in multifamily group therapy in comparison to 31% in adjunctive individual family therapy and 38% in pharmacotherapy group. |</p>

</table>
Men were randomly assigned to behavioral couples therapy (BCT), individual-based treatment (IBT), or couples-based psychoeducational attention control treatment (PACT). BCT resulted in greater improvements in parents’ dyadic adjustment and fathers’ substance use.

</table>
| 2.19 | Fals-Stewart and Clinton-Sherrod (2009) | RTC study evaluating the effects of Individual Based Treatment (IBT) vs. Partner Involved Behavioural Couples Therapy (BCT) on relationship between substance misuse and intimate partner violence among substance misusing men. | Recruited 207 couples  *BCT (n = 103 couples)*  Female partners' age 31.6 (SD 6.4)  Male partner's age 32.8 (SD 7.1)  *IBT (n = 104 couples)*  Female partners' age 32.0 (7.0)  Male partner's age 33.3 (7.2) | Timeline Followback Interview  Structured Clinical Interview for DSM–IV  Timeline Followback Interview–Spousal Violence | 12 months | • Couples therapy can be effective in reducing important episodes of IPV among substance-abusing couples.  
• 12 month follow up showed that BCT group reported significantly lower levels of IPV and substance misuse than IBT group with male partners.  
• BCT group demonstrated lower likelihood of male-to-female IPV on days of substance use than IBT group in which the male partners received IBT |
| 2.20 | Fals-Stewart and Lam (2008) | RTC study evaluating efficacy and cost effectiveness of a Brief Version of Behavioral Couples Therapy (B-CBT) vs. standard Behavioral Couples Therapy (BCT) vs. Individual Based Therapy (IBT) vs. Psycho-educational Attention Control Treatment (PACT) for couples in which one of the partners meets the DSM IV criteria for substance misuse disorder. | 184 couples recruited  **B-CBT (n = 47)**  Mean age 29.4 years (SD 4.8)  Partners’ mean age 28 years (SD 4.5)  **BCT (n =46)**  Mean age 31 years (SD 5.2)  Partners’ mean age 27.9 years (SD 5.0)  **IBT (n = 46)**  Mean age 30.1 years (SD 4.7)  Partners’ mean age 29.1 years (SD 4.7)  **PACT (n = 46)**  Mean age 32.7 years (SD 5.0)  Partners’ mean age 30.2 years (SD 4.5) | The Timeline Followback Interview  Structured Clinical Interview for DSM–IV  The Dyadic Adjustment Scale  Global Rating Scales of Adherence and competence  The Client Satisfaction Questionnaire | Every 3 months for 1 year | • BCT and B-CBT had equivalent post treatment and 12-month post treatment substance use outcomes.  
• The percentage of days abstinent increased from 36.2 at pre treatment to 93.7 at post treatment for B-CBT therapy.  
• Similar results were obtained for BCT (38.3 vs. 94.1), IBT (37 vs. 88.3) and PACT (34 vs. 89.6)  
• Participants in the B-CBT condition showed significantly higher dyadic adjustment than those in IBT or PACT  
• Participants in the B-CBT condition showed significantly reduced substance use frequency when compared to participants in IBT or PACT conditions. |
| 2.21 | Fals-Stewart, O’Farrell et al. (2009) US | RCT study evaluating effectiveness of Behavioral Couples Therapy (BCT) plus Individual-Based Treatment (IBT) vs. Individual-Based Treatment (IBT) for gay couples in which one of the partners has alcohol use disorder (AUD). | 100 gay couples recruited  n = 48 females Mean age 27.72 years (SD 4.36) Partners’ mean age 29.43 years (SD 4.28) n = 52 males Mean age 31.31 years (SD 5.46) Partners’ mean age 30 years (SD 4.09) | Timeline Followback Interview (TLFB) Structured Clinical Interview for DSM-IV Dyadic Adjustment Scale (DAS) The Client Satisfaction Questionnaire (CSQ-8) | 3 months 6 months 9 months 12 months | • Participants with AUD who received BCT reported significantly lower percentage of days of heavy drinking during the year after treatment than those who received IBT only. • Results were maintained at 1 year follow up. • Couples who received BCT reported higher levels of relationship adjustment at the end of treatment and in the year after treatment than those who received IBT. • Results in the study are consistent with studies conducted with heterosexual couples. |
| 2.22 | Lam, Fals–Stewart et al. (2008) UK | RCT pilot study investigating the effects of Parent Skills Training with Behavioral Couples Therapy (PSBCT) vs. Behavioral Couples Therapy vs. Individual Based Treatment (IBT) for men with alcohol use disorder entering outpatient alcohol treatment, their female partners and a child. | n = 30 (father–mother–child triads) 100% male PSBCT (n = 10) Patient’s mean age 33.4 (SD 5.1) Partner’s mean age 33.2 (SD 5.4) Child’s mean age 8.9 (SD 2.1) BCT (n = 10) Patient’s mean age 34.6 (SD 4.9) Partner’s mean age 32.8 (SD 5.4) Child’s mean age 9 (SD 2) IBT (n = 10) Patient’s mean age 34.2 (SD 4.4) Partner’s mean age 33.1 (5.2) Child’s mean age 8.8 (2.2) | Child Behavior Checklist (CBCL) Children’s Depression Inventory (CDI) Revised Children’s Manifest Anxiety Scale (RCMAS) Timeline Followback Interview (TLFB) | 6 months 12 months | • Preliminary results indicate that adding parenting skills to BCT for alcoholism may improve child behaviour. • Reported clinically significant differences favouring PSBCT therapy over BCT and IBT therapies. • Only PSBCT showed significant improvement on all child outcome measures (p < .05) throughout the 12 months follow up. • While BCT showed significant improvement on all child outcome measures (p < .05), only parent-report of externalizing behaviours were sustained at 6-
| 2.23 | Lam, Fals-Stewart et al. (2009) USA | Randomised study investigating the effects of Parental Skills with Behavioural Couples Therapy (PSBCT) vs. Behavioural Couples Therapy (BCT) vs. Individual Based Treatment (IBT) for families with fathers with alcohol use disorder. Recruited 30 couples who had a child between the ages of 8 and 12 years. **PSBCT** (n = 10) Mean age 33.4 (SD 5.1) 100% male Partner’s mean age 33.2 (SD 5.4) **BCT** (n = 10) Mean age 34.6 (SD 4.9) 100% male Partner’s mean age 32.8 (SD 5.4) **IBT** (n = 10) Mean age 34.2 (SD 4.4) 100% male Partner’s mean age 33.1 (SD 5.2) | Timeline Followback Interview (TLFB) Timeline Followback Interview–Spousal Violence (TLFB-SV) Dyadic Adjustment Scale Parenting Scale Parental Monitoring Scale | 6 months 12 months | • PSBCT and BCT are equally effective in reducing substance abuse and conflict in family. Both treatments showed clinically meaningful effects when compared to IBT therapy. • All treatment groups reported clinically significant improvements in dyadic adjustments at post tests. However, only PSBCT and BCT groups maintained significant treatment gains at 12 month follow up. • Reported significant changes in parenting in PSBCT and BCT groups. • Both groups showed decreased involvement of Child Protection Services with treatment gains maintained at 12 month follow up. |
| 2.24 | McCrady, Epstein et al. (2009) USA | RCT study evaluating efficacy of Alcohol Behavioral Couple Therapy (ABCT) vs. Alcohol Behavioral Individual Therapy (ABIT) for females with Alcohol Use Disorder (AUD). n = 102 women and their male partners **ABCT** (n = 50) Mean age 44.78 (SD 9.14) Partners’ mean age 47.96 (SD 9.56) **ABIT** (n = 52) Mean age 45.31 (SD 9.31) Partners’ mean age 48.98 (SD 11.08) | Timeline Follow Back Interview (TLFB) Daily Drinking Log (DDL) SCID alcohol and drug use disorders modules MCTS Drinking Patterns Questionnaire (DPQ) DAS MATCH Treatment Rating Scale (modified version) | Every 3 months for 18 months | • Results indicate greater efficacy of couple rather than individual treatment for women with alcohol problems. • Results indicate that women increased their percentage of days abstinent (PDA) and reduced heavy drinking (PDH) with significantly greater improvements in ABCT than in ABIT (d = 0.59 for PDA; d = 0.79 for PDH) • At follow-up, the ABCT group |
| 2.25 | O’Farrell, Murphy et al.(2008) USA | RCT pilot study evaluating the effectiveness of Brief Family Treatment (BFT) vs. Treatment as Usual (TAU) on continuing care attendance for alcohol dependent patients in inpatient detoxification. | n = 45  
BFT (n = 24)  
Mean age 48.1 years (SD 7.8)  
100% male  
TAU (n = 21)  
Mean age 47.4 years (SD 9.3)  
90.5 % females | Drug and Alcohol Program Treatment Inventory (DAPTI)  
Timeline followback (TLFB) interview  
Patients’ electronic medical records  
Patients’ DSM-IV assessment  
Outcomes:  
Enter to continuing care post detoxification  
Continuing care attendance | 3 months | Results indicate that family involvement in discharge planning may contribute to decreased alcohol use and increased care attendance post detoxification.  
Alcohol dependent patients in BFT group were more likely to enter a continuing care programme than alcohol dependent patients in TAU group.  
92% of participants in BFT group entered a continuing care programme after detoxification in comparison to 62% in TAU group (medium to large effect size)  
2/3 of BFT participants had fewer days of alcohol use than TAU participants (small to medium effect size) |
| 2.26 | Templeton (2009) UK | Before-after study evaluating the impact of a brief structured intervention for family members affected by relatives’ substance misuse. | n = 12  
8 females  
4 males | Four questionnaires, see (Orford et al., 2005b).  
Primary outcomes:  
Health (physical and psychological symptoms) | End of treatment | 5 step interventions can be successfully integrated into group programmes for family members.  
Reported significant improvement changes in health of family |
| 2.27 | Vedel, Emmelkamp et al. (2008) The Netherlands | RCT study examining the effectiveness of Behavioral Couples Therapy (BCT) vs. individual Cognitive Behavioral Therapy (CBT) for males and females with alcohol disorder and their partners. | **BCT (n = 30)**
Mean age 45.4 years (SD 12.34)
26 males

**CBT (n = 34)**
Mean age 45.6 years (10.56)
29 male | Structured Clinical Interview for DSM-IV Axis I Disorders (SCID-I)
European Addiction Severity Index (EuropASI)
Alcohol Use Disorders Identification Test
Situational Confidence Questionnaire (SCQ)
Maudsley Marital Questionnaire (MMQ)
Level of Expressed Emotion Questionnaire (LEE) | 6 months |
• BCT and CBT are equally effective in changing drinking behaviour after treatment.
• Reported reduction in drinking from an average of 45 U per week to an average of 4 U week for CBT and from an average of 41 U per week to and average of 1 U per week for BCT (p < 0.001)
• However, BCT group reported increased levels of marital satisfaction when compared to CBT group.
• Conclusion: both CBT and BCT can be used successfully for treatment of alcohol disorders. |

| 2.28 | Schumm, O’Farrell et al. (2009) USA | Before and after comparison study examining the effect of Behavioural Couples Therapy (BCT) on partner violence in female alcoholic patients and their partners. | BCT group (n = 103 )
Mean age 39.96 years (SD 8.10)
Male partner’s mean age 42.23 years (SD 9.30)

Comparison group (n = 103)
 n = 103
Mean age 39.83 years (SD 8.14)
Male partner’s mean age 42.21 years (SD 9.52) | In-person interviews (drinking measures)
Conflict Tactics Scale (CTS)
Timeline Follow-Back interview (TLFB) | 1 year |
• BCT therapy is effective in reducing the levels of partner violence.
• There was a significant decrease in partner violence from pre (68%) to post (31%) treatment. 1 year after receiving BCT intervention.
• 45% of participants demonstrated abstinence or minimal substance uses at 1 year
| 2.29 | Li, Armstrong et al. (2007) | Canada | RCT pilot study investigating the efficacy of BCT (Multiple Couples Treatment or MCT) vs. Individual Couple Treatment (ICT) for couples with substance abuse problems. | MCT 15 couples \( (n = 30) \)  
Mean age 43.62 (SD 9.3)  
Gender of substance abuser 67% male  
ICT 12 couples \( (n = 24) \)  
Mean age 40.36 (SD 8.6)  
Gender of substance abuser 75% male | Dyadic Adjustment Scale (DA)  
Brief Symptom Inventory (BSI)  
Alcohol and Drug Use Information Form  
Adverse Consequences of Drug Use Scale (ACDU)  
Client Satisfaction Questionnaire (CSQ) | 6 months | Group and Individual BCT treatments can be successfully used as a treatment for couples with substance abuse problems.  
Male participants in both treatment groups and females in MCT group reported improvement in marital relationships.  
Participants in ICT and MCT groups demonstrated improvement in emotional functioning.  
67% of substance users were able to meet their drug use goals following the treatment. |}

| 2.30 | Haggerty, Skinner et al. (2008) | USA | RCT study evaluating efficacy of the Focus on Families (FOF) preventive intervention combined with methadone clinic treatment vs. methadone clinic treatment alone for reducing substance use disorders among children in families in which a child is substance using. | 133 families:  
Parents  
\( n = 144 \)  
Mean age 35.3 (SD 5.8)  
75% mothers  
Children | Composite International Diagnostic Interview (CIDI) | 12 - 15 years | Intervention and control participants did not differ significantly in risk of developing substance use disorders  
However, the impact of the intervention was different for boys and girls. There was significant reduction in the risk of developing substance use disorders. |
parent undergoes methadone treatment. | n = 177  
Mean age 8.21 (SD 3.9)  
56.84% male  
**FOF** *(n = 75)*  
including 82 parents and 95 children  
(mean age 8.2 years)  
**Methadone** *(n = 55)*  
including 62 parents and 82 children  
(mean age 8.2 years) | of developing a substance use disorder for intervention group males vs control group males  
(hazard ratio = 0.53, *P* = 0.03)  
• FOF may have long-term positive effects on reducing substance use disorders among male children

| 3.6 | Bradley, Couchman et al. (2006) Australia | RCT evaluating the efficacy of multiple-family group treatment (MFGT) vs. case management (Control) in the treatment of schizophrenia | **Control Group (n = 8)**  
Mean age 29.38 years (SD 4.5)  
62.5% male  
Mean age at onset of schizophrenia 22.75 years (SD 6.96) | **MFGT (n = 25)**  
Mean age 33.6 years (SD 6.68)  
72% female |  **Brief Psychiatric Rating Scale**  
**Scale for the Assessment of Negative Symptoms**  
**Health of the Nation Outcome Scale**  
**Quality of Life Scale**  
**Family Burden Scale** | 18 months | • Significantly reduced rates of relapse after treatment for MFGT group, compared to control group (12% vs. 36%)  
• Similar story for relapse rates at follow-up (25% vs. 63%)  
• Significantly reduced BPRS ratings for MFGT group  
• Improved vocational outcomes for MFGT group |
| 3.7 | McDonell, Short et al. (2006) USA | RCT examining the effects of multiple-family group treatment (MFGT) on outpatient and inpatient mental health service utilization of 97 persons with schizophrenia | **Treatment group, standard care plus MFGT (n = 53)**  
Mean age 31.9 years (SD 8.7)  
77% male  
**Control group, standard care (n = 44)**  
Mean age 33.8 years (SD 10.2)  
79% male |  **Service utilisation**  
**Clinical status - Structured Clinical Interview for the DSM-IV, Psychotic Disorders Version**, **Brief Psychiatric Rating Scale (BPRS; Overall & Gorham, 1962)** and the **modified Scale for the Assessment of Negative Symptoms** | 1 year | • MFGT participants demonstrated a significant increase in outpatient utilization as a direct consequence of the intervention. However, when service use was summed across 3 years post-randomization, no group differences were observed  
• Results suggest that implementation of MFGT in a community mental health setting reduces inpatient service at specific time periods, without significantly increasing outpatient service utilization |

- Psychoeducational multiple-family group intervention was more effective than standard care in managing negative symptoms over a 12-month period.

### 3.20
**Montero, Masanet et al. (2006) Spain**

Follow-up study to Montero, Asencio et al. (2001) over a 5-year period on 87 patients diagnosed with schizophrenia and their families taking part in a cognitive behavioural therapy, assigned at random either to (a) a family unit including the patient or (b) a group of relatives, to assess whether the clinical and social benefits observed in the short term would be maintained 5 years later.

<table>
<thead>
<tr>
<th>Patient Description</th>
<th>Relapse</th>
<th>Readmissions</th>
</tr>
</thead>
<tbody>
<tr>
<td>87 patients of both genders, who had been diagnosed with schizophrenia (DSM-III) and their respective families</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

- Long-term outcomes for both groups were similar.
- Survival analysis indicated that there were no significant differences between the two groups with regards to either relapse or readmissions.
| 3.21 | Bressi, Manenti et al. (2007)  
*Italy* | Longitudinal prospective study evaluating the effectiveness of systemic family therapy (SFT) vs. control case sample of routine psychiatric care (PC) in 40 patients with schizophrenia | SFT; n=20  
PC; n=20 | Hospital readmissions  
Relapse and pharmacological compliance | 12 months  
Two years | - At follow-up, improved clinical course and a better pharmacological compliance seen in SFT group  
- 15% of SFT group had relapsed, compared to 65% in PC group (p = 0.03)  
- No significant difference at 2-year follow-up |
| 3.22 | Motlova, Dragomirecka et al. (2006)  
*Czech Republic* | Non-randomised controlled study examining the effectiveness of a family psychoeducation intervention (site A) vs. no treatment (site B) in schizophrenia management | *Intervention group* (n = 53)  
Mean age 31.13 years (SD 10.23)  
37.7% male  
*No treatment group* (n = 67)  
Mean age 32.39 years (SD 9.81)  
54% male | Relapse rate  
Global Assessment Functioning  
Psychoeducation Outcomes Questionnaire | 12 months | - Psychoeducation group had a shorter average length of rehospitalisation stay at 12-month follow-up, compared to no treatment group  
- At 12-month follow-up, the probability of rehospitalization higher for patients from no treatment group |
| 3.23 | Yamaguchi, Takahashi et al. (2006)  
*Japan* | Before-after study examining outcomes for short-term multi-family psychoeducation groups for relatives of patients with schizophrenia | 37 patients with schizophrenia and 46 of their relatives recruited  
Mean age of patients 25.1 years  
Mean age of relatives 52.7 years | Expressed Emotion  
Anxiety, burden and stress levels in families - Family Burden and Distress Scale;  
State-Trait Anxiety Inventory | Six months | - Both state and trait anxiety on the State-Trait Anxiety Inventory were significantly lower after intervention compared to before intervention  
- Subjective burden and distress reported by the family significantly decreased on the subscales for family confusion resulting from a lack of knowledge of the illness and anxiety about the future, subjective burden and depression resulting from the patient’s illness, and difficulties in the relatives’ relationships with the patient. |
| 3.24 | Stanbridge, Burbach et al. | 3.25 | Gutie´rrez Maldonado,Caqueo-Uri zar et al. (2009) Chile | RCT evaluating the effect of Family Psychoeducational Program plus treatment as usual vs. treatment as usual alone on changing attitudes towards schizophrenia and health perceptions of relatives of patients with schizophrenia. | N = 41 caregivers Mean age 54.2 years (SD 15) 31 women | Relatives’ Attitudes toward Schizophrenia SF-36 General Health Questionnaire | End of treatment |
|      |                                     |                                                                           | Psychoeducational Intervention (n = 18) Control group (n = 23) | Outcomes: Caregivers’ attitudes towards schizophrenia Caregivers’ health perceptions | The psychoeducational program is more effective than treatment as usual in reducing negative attitudes of caregivers of patients with schizophrenia. Caregivers in the experimental group demonstrated significantly lower scores on the attitude questionnaire (from pre test at 108.6 to post test at 83.9). Treatment as usual alone did not have significant impact on modifying negative attitudes in the control group with no significant difference in scores from pre test (105.7) to post test (109.4) Family intervention was more effective among relatives of female patients. Family intervention did not have a significant effect on caregivers’ health perceptions. |
| 3.26 | **Kulhara, Chakrabarti et al. (2008) India** | RCT study evaluating the impact of Structured Psychoeducational Intervention vs. routine out patient care for caregivers of Indian patients diagnosed with schizophrenia. | Recruited 76 patients with diagnosed schizophrenia and 76 caregivers.  
**Structured Psychoeducational Intervention (n = 38)**  
Mean age 31.1 years (SD 11.5)  
17 males  
Caregivers (n = 38)  
Mean age 47.7 years (SD 13)  
32 males  
**Routine out patient care (n = 38)**  
Mean age 31.6 years (SD 9.8)  
25 males  
Caregivers n = 38  
Mean age 46.3 years (SD 13)  
25 males | Structured Clinical Interview for DSM-IV axis I disorders – Clinician Version Positive and Negative Syndrome Scale (PANSS)  
WHO Disability Assessment Schedule for Assessment of Psychiatric Disability  
Social Support Scale  
Patient Satisfaction Questionnaire  
Family Burden Interview Schedule of Pai and Kapoor coping checklist | **End of treatment**  
- Structured Psychoeducational Intervention was significantly better than routine out-patient care among Indian out-patients with schizophrenia and their caregivers.  
- Structured Psychoeducational Intervention was more effective in reducing psychopathology, and disability levels when compared to routine out patient treatment.  
- Structured Psychoeducational Intervention showed better outcomes in perception of social support and satisfaction with treatment among caregivers when compared to standard treatment.  
- However, Structured Psychoeducational Intervention did not significantly reduce drop-out, relapse and caregiver-burden, or improve caregiver-coping. |

| RCT evaluating the efficacy of family intervention vs. two control groups (interview control group and no interview control group) in reducing the subjective burden of care in caregivers of patients with Alzheimer’s Disease and producing clinical benefits in patients | Family Intervention (n = 13)
- Mean age of carers 69.6 years (SD 15.2)
- Mean age of patients 76.6 years (SD 9.3)
- Carer gender 30.8% male
- Patient gender 23% male

Interview Control Group (n = 14)
- Mean age of carers 63.0 years (SD 14.0)
- Mean age of patients 76.3 years (SD 10.6) |

Caregiver assessments – General Health Questionnaire and Beck Depression Inventory
- Knowledge about dementia

Patient assessments – Mini-Mental State Examination, Cornell Scale for Depression in Dementia, MOUSEPAD, Clinical Dementia Rating. |

Post-treatment, 9 months after trial entry 3 month follow-up, 12 months after entry into trial |

- Significant reductions in distress and depression in the intervention group compared with control groups at post-treatment and follow-up
- Significant reductions in behavioural disturbance at post-treatment and an increase in activities at 3 mo in patients in the intervention

were receiving individual therapy when recruited.

10 couples (n = 20)
- Age range 25 to 53 years
- Mean age 40 years |

Dyadic Adjustment Scale
- Beck Depression Inventory-II
- State-Trait Anger Expression Inventory – Revised
- Difficulties in Emotion Regulation Scale
- Difficulties in Emotion Regulation Scale – partner version

Positive and Negative Affect Schedule
- Efficacy Questionnaire
- Client Satisfaction Questionnaire |

Change was reported for DBT graduates (even after 6 month follow up)

- DBT graduates reported significantly less depression and the effect was maintained at 6 month follow up.
- Treatment had no effect on anxiety in DBT graduates
- Decreased positive and negative affect at post treatment in DBT graduates
- Reported increased affect regulation abilities in DBT graduates
| 32.3 | MacDonald (2005) UK | Outcomes from a solution-focused brief therapy outpatient clinic in adult mental health are described. | Seventy-five clients were referred, of whom fifty-three were seen and forty-one traced at follow-up | Patient Satisfaction | A questionnaire was sent to clients and their family doctors one year after they ceased to attend | good outcome was found in thirty-one cases (76%), while ten clients (24%) reported no improvement. A good outcome was reported in twelve of the sixteen clients with anxiety or tension, seven out of seven who wanted ‘something new in their lives’, six of the eight with relationship difficulties, three of the five with depressive complaints and the two with problems involving violence. |
| 14.1 | Sytema and Bout (2006) *The Netherlands* | Cohort study of 173 couples looking at the outcomes of an inpatient group treatment programme for couples with complicated problems that require intensive therapy | Mean age of males 51.7 years (SD 9.6)  
Mean age of females 49.1 years (SD 9.5) | ICD-10 Symptom Check List (SCL-90)  
Interactional Problem Solving Inventory | Post-treatment 6 months  
18 months | Outcomes indicate that clinical group therapy for these couples is effective |
| 14.3 | Weine, Kulauzovic et al. (2008) *USA* | RCT study evaluating the effects of family focused intervention (Coffee and Families Education and Support - CAFES) vs. control group on increasing access to mental health for refugees with Post-traumatic Stress Disorder (PTSD). | Recruited 197 Bosnian refugees with PTSD and their relatives  
*CAFES (n = 110)*  
Mean age 38.5 years (SD 10.4)  
45.5% males  
*Control (n = 87)*  
Mean age 36.7 (SD 9.0)  
54.5% males  
Family member  
Mean age 35.5 (SD 9.8)  
60% females | PTSD Symptoms Scale  
Center for Epidemiological Studies Depression Scale  
Knowledge regarding trauma mental health (questionnaire)  
Scale assessing family comfort (discussing trauma mental health)  
Outcomes:  
Severity of depression  
Family comfort discussing trauma mental health  
Severity of PTSD symptoms  
Traumatic events  
Knowledge about trauma mental health | 6 months  
12 months  
18 months | Multiple family group intervention (CAFES) is effective in increasing access to mental health services for refugees diagnosed with PTSD.  
CAFES intervention group reported significantly higher number of mental health visits than control group.  
By contrast, PTSD symptoms do not account for the number of mental health visits in both CAFES and control groups.  
Similarly, knowledge about trauma mental health did not seem to facilitate access to mental health services.  
Reported that depression scores and family comfort with discussing trauma mediated the effect of the intervention. |
| 14.4 | Anderson, Huff et al. (2008) *USA* | Qualitative study using grounded theory approach to examine the process of conducting Medical Family Therapy (MedFT) in an inpatient psychiatric system. The recruited patients, their families, referring providers and family therapists. | Interviews | n/a | • Results provide support for integrating MedFT into treatment at psychiatric inpatient settings.  
• Patients, family members, |
Analysis is based on 15 case studies.

**MedFT** helps patients and their families to initiate systemic changes in order to reduce further hospitalisations. MedFT is also effective in dealing with complex family dynamics, related to hospitalisation. Results indicate that high levels of collaboration with the patient, family members and referring providers make MedFT especially effective.

| 8.1   | Uncontrolled outcome pilot study, examining the benefits of multiple family group therapy for patients with chronic pain and their relatives | 19 patients with chronic pain as defined by DSM-IV and 41 relatives Mean age of patients 34.6 years (SD 15.3) 11% male (patients) 58.5% male (relatives) | Symptom Checklist (SCL-90) Multidimensional Pain Inventory (MPI) Family Climate Scale (GKS-II) Group Evaluation Questionnaire | Not stated | - Patients showed a significant increase in life control and social activities, and a significant decrease in affective distress on the MPI-DLV  
- Significant reduction in depression and feeling on insufficiency on the SCL-90  
- On the GKS-II, family members showed a positive change for measures of organisation and control  
- On the Group Evaluation Questionnaire, 87.5% of patients found the treatment to be helpful for themselves, whereas 81.2% of patients found the treatment to be helpful for family members |
| 9.1   | RCT assessing the efficacy of structural ecosystems therapy (SET) vs. attention-comparison person-centred condition vs. community control group for HIV-positive African-American women | 209 HIV-positive females recruited Mean age of total sample 36 years (SD 8) | Psychological distress - Global Severity Index from the Brief Symptom Inventory Family hassles - The Hassles Scale Family support - Social Support Questionnaire | 3 months 6 months 9 months 18 months | - Growth curve analyses over 5 time points revealed that SET was more efficacious than either of the control conditions in reducing psychological distress and family-related hassles  
- SET was not more efficacious in increasing family support  
- Latent growth mixture modelling analyses indicated that SET was most efficacious for women who, on average, were at or near the clinical threshold for psychological distress and for women with high levels of family hassles |
| 10.1 | Kissane, McKenzie et al. (2006) *Australia* | RCT examining the efficacy of family-focused grief therapy vs. control group for families of patients dying of cancer | Family-focused grief therapy (53 families, 233 individuals) | Family Environment Scale – measure of family functioning | 6 months 13 months | - Small overall impact of family focused grief therapy - reduction in distress at 13 months  
- Significant improvements in distress and depression occurred among individuals with high baseline scores on the Brief Symptom Inventory and Beck Depression Inventory  
- Global family functioning did not change |
| 10.2 | Hudson, Aranda et al. (2005) *Australia* | RCT evaluating effectiveness of standard palliative care plus psychoeducational intervention vs. standard palliative care for family caregivers of patients dying of cancer at home | 106 caregivers recruited | Preparedness for Caregiving Scale  
Caregiver Competence Scale  
Rewards of Caregiving Scale  
Hospital Anxiety and Depression Scale | Time 1 – start of intervention  
Time 2 - 5 weeks  
Time 3 - 8 weeks following patient death | - No intervention effects seen with respect to preparedness to care, self-efficacy, competence, and anxiety  
- Intervention group reported a significantly more positive caregiver experience than those who received standard care at both Times 2 and 3 |
| 10.3 | Manne, Ostroff et al. (2005) *USA* | RCT evaluating efficacy of a couple-focused group intervention (treatment group) vs. usual care (control group) on psychological adaptation of women with early stage breast cancer | Treatment group (n = 120)  
Mean age 49.25 years (SD 10.4)  
100% female  
Control group (n = 118)  
Mean age 49.76 (SD 10.5)  
100% female | General distress - Mental Health Inventory—18  
Cancer-specific distress - Impact of Event Scale  
Partner unsupportive behaviours – Partner Unsupportive Behaviors Scale  
Physical impairment - Functional Status subscale of the Cancer Rehabilitation Evaluation System  
Treatment expectancy - A modified Expectancy Rating Form  
Treatment evaluation - A 20-item expanded version of Borkovec and Nau’s (1972) scale  
Psychosocial care use  
Medical variables | Time 2 - 1 week post-intervention  
Time 3 - 6 months post-intervention | - Intent-to-treat analyses indicated that the treatment group reported lower depressive symptoms  
- Subgroup analyses showed that women in the treatment group had significantly less distress than did women receiving usual care and women who dropped out of the intervention |

</tbody>
</table>

- From baseline to 4 months, significantly fewer days of substance use were found for the family therapy alone and the combined interventions.
- Significantly more youths had achieved minimal use levels in the family and combined conditions and in CBT.
- From baseline to 7 months, reductions in percentage of days of use were significant for the combined and group interventions, and changes in minimal use levels were significant for the family, combined, and group interventions.

- Significant reductions in substance use and related problems in both groups, but treatments did not differ at 3 and 6 months following baseline.
- Both groups effective with adolescents with substance abuse, as participants in both conditions were significantly more likely to be in symptom remission or abstinent at follow-up interviews compared to baseline.

- MDFT was significantly more effective than peer group therapy in reducing risk and promoting protective processes in the individual, family, peer, and school domains.
- MDFT more effective in reducing substance use over the course of treatment.

Anglo T and Hispanic A (n = 29)  
Hispanic T and Anglo A (n = 15)  
Anglo T and Anglo A (n = 29)  
T – therapist  
A – Adolescent | Ethic match  
Timeline Follow-Back interview  
Comparability of composite substance measure across ethnic groups  
Urine screen  
Child Behavior Checklist | 4 months | Both Hispanic and Anglo adolescents demonstrated significant reduction in substance use (% days used) following FFT therapy.  
Hispanic adolescents who were ethically matched with therapists demonstrated longer maintenance of treatment gains at 4 month follow up than Anglo adolescents who showed signs of relapse.  
By contrast, ethnic matching did not influence treatment outcomes in Anglo adolescents.  
Conclusion: Ethnic matching between clients and therapists can improve treatment outcomes for Hispanic adolescents with substance misuse problems. |

81% male  
MDFT (n=112)  
Mean age 15.3 (SD 1.25)  
82% male  
CBT (n=112)  
Mean age 15.5 (SD 1.21)  
80% male  
Diagnostic Interview for Children (DISC)  
Personal experience inventory (PEI)  
Time-line follow-back method (TLFB)  
Outcomes:  
substance use problem severity  
30-day frequency of cannabis use  
30-day frequency of alcohol use  
30-day frequency of other drug use  
30-day abstinence.  
6 months  
12 months | Both CBT and MDFT treatments can be successfully used in treating adolescent substance abuse.  
CBT and MDFT showed equivalent reductions in frequency of cannabis use from pre tests (10.41, SD 11.38 and 11.89, SD 11) to 6 month follow up (4.30 and 6.61)  
MDFT was more effective in reducing severity of drug abuse when compared to CBT. |
| 16.20 | French, Zavala et al. (2008) | A cost-effectiveness analysis of four interventions, including family-based, individual, and group cognitive behavioral approaches, for adolescents with a substance use disorder | 114 adolescents recruited, aged 13-17 years  
80% male  
Percentage of days of marijuana use and days of any drug use - Timeline Follow-Back Interview  
Cost effectiveness - adolescent marijuana use and delinquency scores  
4 months  
7 months | • Variation in treatment costs according to intervention  
• At 4-month follow-up, significantly improved substance use outcomes in family therapy group compared to group treatment  
• At 7-month follow-up, substance use outcomes similar for all interventions  
• At 4- and 7-month follow-up, delinquency outcomes similar for all interventions  
• Results suggest that group intervention, the least expensive intervention, was the most cost-effective  
• Difficulties encountered in calculating economic evaluation. |

### Long-term family therapy

#### 18.6
Lock, Agras et al. (2005)

**RCT examining the efficacy of short term family therapy vs. long-term family therapy in the treatment of adolescents with anorexia nervosa**

- **86 adolescents aged 12-18 years recruited**
- **Eating Disorder Examination BMI**

- Mean age 17.58 years (SD 3.37)
- Mean BMI 16.45 (SD 0.85)

- Good outcomes: body weight increased to within 10% of the patient’s average body weight; no bulimic symptoms; a minimum weight gain of 4 kilograms; and menstrual cycle resumed
- Intermediate outcomes: body weight increased to within 10% of the patient’s average body weight; amenorrhoea occurred; bulimic symptoms present but occurring less than once per week; minimum weight gain of 4 kilograms
- Poor outcomes: body weight less than 15% of the patient’s average body weight; bulimic symptoms occurred at least once per week

- Overall functioning: Morgan-

- 12 months

#### 18.7
Ball and Mitchell (2004) Australia

**RCT examining the effectiveness of cognitive behavioural therapy (CBT) vs. behavioural family therapy (BFT) in the treatment of 25 adolescents with anorexia nervosa**

- **CBT (n = 13)**
  - Mean age 18.45 years (SD 2.57)
  - Mean BMI 16.06 (SD 1.58)
- **BFT (n = 12)**
  - Mean age 17.58 years (SD 3.37)
  - Mean BMI 16.45 (SD 0.85)

- Post-treatment 6 months

- 60% of total sample and 72% of treatment completers had “good” outcome at post-treatment and at six months follow-up
- No significant differences between treatment groups were found and the majority of patients did not reach symptomatic recovery

</table>
| 18.8 | Eisler, Dare et al. (2000) *UK* | RCT assessing the efficacy of two outpatient family interventions, conjoint family therapy (CFT) vs. separated family therapy (SFT), for adolescents with anorexia nervosa | CFT *(n = 19)*  
Mean age 15.5 years  
Mean duration of illness 13.9 months  
SFT *(n = 21)*  
Mean age 15.5 years  
Mean duration of illness 12.0 months | Individual Assessment Measures  
Mood – Short Mood and Feeling Questionnaires  
Self-esteem – Rosenberg Self Esteem Inventory  
Obsessional phenomena – Maudsley Obsessional Compulsive Index  
Eating disturbance – Eating Attitude Test; Eating Disorder Inventory  
Weight  
Family Measures  
Family Adaptability and Cohesion Evaluation Scales  
Standardized Clinical Family Interview | 3 months  
6 months  
End of treatment | • Considerable improvement in nutritional and psychological state in both groups  
• On global measure of outcome, the 2 forms of therapy were associated with equivalent end of treatment results. However, for those patients with high levels of maternal criticism towards the patient, the SFT was shown to be superior to the CFT  
• Symptomatic change was more marked in the SFT whereas there was considerably more psychological change in the CFT group. There were significant changes in family measures of Expressed Emotion. Critical comments between parents and patient were significantly reduced and that between parents was also diminished. Warmth between parents increased |
| 18.9 | Geist, Heinmaa et al. (2000) | RCT examining efficacy of family therapy vs. family psychoeducation on 25 females aged 12-17.3 years with newly diagnosed restrictive eating disorders requiring hospitalisation | 25 females recruited  
Mean age = 14.3 | Medical outcomes – body weight  
Psychosocial outcomes – specific and non-specific eating disorder psychopathology  
Family Assessment measure  
Diagnostic Interview for Children & Adults  
Eating disorders inventory  
Children’s Development Inventory  
Brief Symptoms Inventory | Every 2 weeks until 4 months after end of treatment | • Significant time effect seen for both groups for restoration of body weight  
• Time effect also seen on the Family Assessment Measure - both groups reported more family psychopathology at the end of treatment  
• No significant group differences were found on any of the self-report measures of specific and non-specific eating disorder pathology  
• Weight restoration reported at 4-month follow-up in both groups, but no significant change was reported in psychological functioning by either adolescents or parents |
| 18.10 | Loeb, Walsh et al. (2007) USA | Uncontrolled outcome study assessing the effectiveness of family-based treatment (FBT; Maudsley model) for adolescents with anorexia nervosa | 20 adolescents (age range 12-17 years) | Percentage of ideal body weight | Menstrual status | Eating Disorder Examination (EDE) subscales scores | Children's Depression Rating Scale-Revised | • 75% completed FBT  
• Intent-to-treat analyses showed significant improvement over time in all outcomes, apart from EDE Shape Concern or Weight Concern subscales or Children's Depression Rating Scale-Revised |
|---|---|---|---|---|---|---|---|---|
| 18.11 | Rhodes and Madden (2005) Australia | Uncontrolled outcome study describing the introduction of the Maudsley model of family-based treatment for anorexia in the Eating Disorders program at a children's hospital over 18-month period | Data on cohort not stated | Readmissions  
Weight | Not stated | • Data on a year-by-year basis suggests improved outcomes  
• Significant reduction in readmissions in the two years prior to introduction of Maudsley Model to two years after introduction of model |
| 18.12 | Scholz and Asen (2001) | Uncontrolled outcome study - description of 18 month follow-up data on 28 adolescents with eating disorders and their families who have received a multi-family approach therapy | Recovery  
Rates of readmissions  
Satisfaction Subjective Family Picture Test | 18 months | • Treatment is acceptable to patients and families  
• Significant positive changes in the patients' symptomatology and recovery rates |
| 18.13 | Fleminger (2005) Netherlands | Case series describing the outcomes from multi family group treatment for adolescents with eating disorders | 5 cases reported | Improvement in symptoms  
Food intake  
Weight | Not stated | Most cases improved with respect to eating disorder symptoms, with increase in food intake and weight |
| 18.14 | Lock, Grange et al. (2006) USA | Retrospective case review reporting on the use of family-based treatment (FBT) with children with anorexia nervosa | 32 children  
Mean age 11.9 years (range 9-12.9 years) | Weight  
Eating Disorder Examination Child self-report scores | After treatment | • Statistically and clinically significant weight gain and eating disordered thinking in children who participated in FBT |
| 18.16 | Krautter and Lock (2004) USA | Survey assessing the satisfaction and perspectives of families who completed treatment using a manual-driven family-based treatment for anorexia nervosa | 34 families who had completed treatment recruited – adolescents with anorexia nervosa and their parents or guardians  
Mean age of adolescents 14.6 years | Patient satisfaction at the end of treatment  
Outpatient effectiveness Inventory | N/A | • The overall effectiveness was rated from 3.97 (adolescent rating) to 4.40 (maternal rating)  
• Adolescents scored therapeutic alliance, psychoeducation about anorexia nervosa, including the whole family in treatment, |
and separation of the illness from the patient as highly effective
- Qualitative results - 78% of participants felt highly positive about family treatment
- 84% of participants perceived a change in their family after treatment
- 84% of participants would recommend this treatment to others

| 18.17 | Paulson-Karlsson, Nevonen et al. (2006) *Sweden* | Survey examining patient satisfaction with family-based treatment for anorexia nervosa in adolescents aged 13-18 years | 32 patients, 41 parents | Treatment satisfaction self-report questionnaire | Questionnaire sent to families at 18-month follow-up | The results show that 73 per cent of the patients and 83 per cent of the parents felt that their pretreatment expectations had been fulfilled. The majority agreed that individual patient sessions and parental sessions were of great help, while the patients valued family therapy sessions as being less helpful than did parents. In overall terms, parents were more pleased with the therapists than were the patients. |

| 21.0  | Cloutier, Manion et al. (2002)  
*Canada* | Follow-up study describing long-term outcomes from an RCT evaluating the efficacy of Emotionally Focused Therapy (EFT) in decreasing marital distress in a sample of couples with a chronically ill child | 13 couples participated in follow-up study (81% of couples in treatment group in original RCT)  
Mean age of husbands 37.7 years (SD 5.1)  
Mean age of wives 35.0 years (SD 4.8)  
Mean age of chronically ill child 6.1 years (SD 3.0)  
Mean duration of child’s illness 4.4 years (SD 2.1) | Marital adjustment - Dyadic Adjustment Scale  
Intimacy in interpersonal relationships – Miller Social Intimacy Scale  
Stress outside the parent-child relationship experienced by parent – Parent Stress Index | 5 months  
2 years | Improvements in marital functioning were not only maintained but, in some cases, enhanced at the 2-year follow-up |
| 21.1  | Kazak, Simms et al. (2005)  
*USA* | RCT evaluating the effectiveness of a new intervention, Surviving Cancer Completely Intervention Program – Newly Diagnosed (SCCIP-ND) vs. treatment as usual for caregivers of children newly diagnosed with cancer | SCCIP-ND (n = 9 families)  
Median age of patient 5.00 years  
Patient gender 44.4% male  
*Treatment as usual (n = 10 families)*  
Median age of patient 4.50 years  
Patient gender 60% male | Acute Stress Disorder Scale  
Impact of Events Scale - Revised  
State-Trait Anxiety Inventory | 2 months | Preliminary outcome data show changes in the desired direction [e.g., reduced anxiety and parental posttraumatic stress symptoms (PTSS)] |

| 23.0 | Mazzone, Battaglia et al. (2009) Italy | Comparison study examining the effectiveness of Cognitive-Behavioural Family Therapy (CBFT) for children with β-thalassaemia major and their caregivers. | CBFT (n = 28)  
Age range 12.79 (± 3.57 years)  
Comparison group (n= 28)  
Age range 12.52 (± 3.48 years) | Wechsler Intelligence Scale for Children (WISC-IV)  
Child Behaviour Checklist (CBCL)  
Multidimensional Anxiety Scale for Children (MASC)  
Children’s Depression Inventory (CDI)  
Emotional Activity Sociability and Shyness (EAS) Scale  
World Health Organization Quality Of Life (WHOQOL)  
Outcomes:  
- compliance to treatment, lessening the emotional burden of disease  
- improving the quality of life of caregivers | Post treatment  
- Majority of β-Thalassaemic children showed good compliance with chelation therapy.  
- On average, Thalassemic patients showed more somatic complaints and separation panic (58.29, 53.36 respectively) when compared to healthy children (53.32,48.18)  
- B-Thalassaemic children and their mothers also showed high emotionality and low sociability.  
- CBFT can be successfully used to improve the compliance with chelation therapy; however, it does not improve the quality of life of caregivers. |

| 23.1 | Prado, Pantin et al. (2007) USA | RCT evaluating the efficacy of Familias Unidas + Parent-Preadolescent Training for HIV Prevention (PATH), a Hispanic-specific, parent-centered intervention, in preventing adolescent substance use and unsafe sexual behaviour | Familias Unidas + PATH (n = 91)  
Mean age 13.36 years (SD 0.67)  
43% male  
ESOL + PATH (n = 84)  
Mean age 13.40 years (SD 0.72)  
50% male  
ESOL + HEART (n = 91)  
Mean age 13.49 years (SD 0.66)  
52% male | Demographics  
Acculturation. The Bicultural Involvement Questionnaire  
Family functioning  
Substance use  
Sexual risk behaviours | 6, 12, 24 and 36 months post-treatment  
- Familias Unidas + PATH effective in preventing and reducing cigarette use, compared to control groups  
- Familias Unidas + PATH effective in reducing substance use compared to ESOL + HEART  
- Familias Unidas + PATH effective in reducing sexual risk behaviour, compared to ESOL + PATH |
| 23.2 | McKay, Chasse et al. (2004) USA | A quasi-experimental comparison study evaluating the effectiveness of a family-based CHAMP intervention (Chicago HIV prevention and Adolescent Mental health Project) on preventing HIV infections among young people living in neighbourhoods with high rates of HIV infection. | Recruited 4th and 5th graders and their care givers.  
CHAMP group (n = 201)  
40% males  
Comparison group (n = 264)  
43% males | Family Decision Making Questionnaire  
Issues Checklist  
Parent interview (adapted from Pittsburgh Youth Study and Chicago Youth Development Study) | Week 2 – pre-test  
Week 11 – post-test  
- Participating in CHAMP may be associated with strengthening parental decision making, increasing comfort in family, communication regarding sensitive topics, and increasing parental HIV/AIDS knowledge  
- Compared to comparison group, parent in CHAMP group more likely to make decisions within the family  
- CHAMP group significantly related to improvements in parental monitoring, family |

| 23.3 | Ellis, Naar-King et al. (2006) | Retrospective case review examining whether multi-systemic therapy (MST) improves regimen adherence and health outcomes in children with perinatally acquired HIV | 19 children participated in program | Regimen adherence Health outcomes | 3 months | • Significant improvement in caregivers' general knowledge of HIV
• No significant change in caregiver-reported adherence
• From referral to end of MST treatment, significant reduction in viral loads
• Most children in study maintained these improvements at 3-month follow-up |
| 24.1 | Glueckauf, Liss et al. (2002) USA | RCT examining the efficacy of issue-specific single-family counselling (IFCM) vs. multi-family psychoeducational group (PE) in adolescents with epilepsy and their parents | 19 adolescents completed study Mean age 13.9 years (SD 1.37) Mean age of mothers 41 years (SD 5.13) IFCM; n = 9 PE; n = 10 | Adolescent and Parent Background Information Forms Working Alliance Inventory 6-point Issue Severity Scale Issue Change Scale Issue Frequency Scale Family Therapy Outcome Index | Not stated | • No overall differences in alliance between the two groups
• Significantly stronger alliance in IFCM, compared to PE
Alliance positively correlated with therapy outcome for adolescents, but not for mothers |
| 25.1 | Bruzese, Unikel et al. (2008) USA | RCT assessing the efficacy of “It’s a Family Affair”, a school-based intervention for adolescents with asthma and their caregivers vs. control group (no treatment) | Mean age of children 12.9 years (SD 0.81) 54% male Intervention; n =12 Control; n = 12 | Asthma management - Asthma Responsibility Questionnaire Asthma symptom severity Caregiver-child interactions - Parent-Adolescent Relationship Questionnaire Delivery of intervention Program evaluation form Satisfaction | Post-treatment 2 months | • At two-month follow-up, caregivers in intervention group showed improved problem-solving with children, compared to control group
• Intervention group participants more responsible for carrying medication, took more prevention steps, and woke fewer nights from asthma
• The intervention resulted in positive short-term changes in family relations, asthma management by students, and health status |
| 25.2 | Ng, Li et al. (2008) | RCT (randomised waitlist-controlled crossover design) evaluating asthma psychoeducation program incorporating family therapy | For patients: exhaled nitric oxide (eNO), spirometry, and adjustment to asthma
For parents: perceived efficacy in asthma management, Hospital Anxiety and Depression Scale anxiety subscale, Body Mind Spirit Well-being Inventory emotion subscale, and Short Form 12 health-related quality of life scale | Short follow-up |
| 26.1 | Naar-King, Ellis et al. (2007) | RCT examining the effectiveness of multisytemic therapy vs. standard multidisciplinary care in decreasing parental overestimation of adolescents’ responsibility for completion of diabetes care | Change in adherence significantly higher in BFST-D group, compared to SC at each follow-up and the ES group at 6 and 18 months
• Significant improvement on effects on A1C in BFST-D group, compared to SC and ES.  
• No significant differences on treatment adherence and family conflict  
• Improvement in A1C appeared to be mediated by improvement in treatment adherence. A significantly higher percentage of BFST-D youth achieved moderate or greater improvement (>0.5 SD) in treatment adherence compared with the SC group at each follow-up and the ES group at 6 and 18 months  
• Change in treatment adherence correlated | 12 months |
| 26.5 | Wysocki, Harris et al. (2007) | RCT examining the efficacy of Behavioral Family Systems Therapy for Diabetes (BFST-D) vs. multifamily educational support group (ES) vs. standard care (SC) in 104 families of adolescents with inadequate control of type 1 diabetes | BFST-D (n = 36)
Mean age 13.9 years (SD 1.9)
58% male
Mean duration of diabetes 5.1 years (SD 3)
ES (n = 36)
Mean age 14.4 years (SD 1.9)
56% male
Mean duration of diabetes 5.5 years (SD 3.2)
SC (n = 32) | A1C - improvement in glycemic control
Hollingshead Index of Social Status
Diabetes Self-Management Profile
The Diabetes Responsibility and Conflict Scale | 6 months (end of treatment) 12 months 18 months |
|  |  | Mean age 13.23 years (SD 1.95) 49% male | Diabetes Family Responsibility Questionnaire
Metabolic control – haemoglobin A1c |  |  |
| 26.2 | Ellis, Templin et al. (2007) USA | RCT examining efficacy of multisystemic therapy (MST) vs. standard care in adolescents with 127 chronically poorly controlled type 1 diabetes | See Ellis, Frey et al. (2005) for details of participants | Adherence to medical regimen – frequency of blood glucose testing Metabolic control – HbA1c, a retrospective measure of average blood glucose over the previous 2-3 months Rates of diabetic ketoacidosis (DKA) admissions – medical records | 6 months | • Intent-to-treat analyses revealed a main effect of MST on DKA admissions was at end of treatment and 6-month follow-up • Improvements in HbA1c for the MST group at treatment termination were lost at follow-up. Results show that intensive, home-based psychotherapy created stable reductions in serious lapses in adherence, as indexed by episodes of DKA, among youth with poorly controlled diabetes |
| 26.3 | Ellis, Yopp et al. (2007) USA | RCT examining efficacy of multisystemic therapy (MST) vs. standard care in adolescents with 127 chronically poorly controlled type 1 diabetes | See Ellis, Frey et al. (2005) for details of participants | Changes in general family relationships – Diabetes Family Behavior Checklist; Family Relationship Index of the Family Environment Scale Caregiver support for diabetes care Adherence – blood glucose meter Metabolic control – HbA1c | 7 months | • MST increased support for diabetes care from both primary and secondary caregivers in two-parent but not in single-parent families. • MST had the strongest effects on BGT and metabolic control in single-parent families. |
| 26.8 | Wysocki, Harris et al. (2006) USA | RCT examining the effectiveness of standard care (SD) vs. educational support (ES) vs. behavioural family systems therapy for diabetes (BFST-D) in adolescents with diabetes and their families | SC (n = 32) Mean age 14.2 years (SD 1.9) 50% male ES (n = 36) Mean age 14.4 years (SD 1.9) 56% male BFST-D (n = 36) Mean age 13.9 years (SD 1.9) 58% male | The Parent–Adolescent Relationship Questionnaire The Diabetes Responsibility and Conflict Scale The Diabetes Self-Management Profile Glycosylated Haemoglobin (HbA1c) | 6 months 12 months | • BFST-D significantly improved family conflict and adherence compared to SC and ES, especially among those with baseline HbA1c equal to or greater than 9.0% • BFST-D and ES significantly improved HbA1c compared to SC among those with baseline HbA1c equal to or greater than 9.0% |
| 26.6 | Ellis, Frey et al. (2005) USA | RCT examining efficacy of multisystemic therapy (MST) vs. standard care in adolescents with 127 chronically poorly controlled type 1 diabetes | **MST (n = 64)**  
Mean age of adolescent 13.4 years (SD 1.9)  
Mean age of parent 39.7 years (SD 7.7)  
Mean duration of diabetes 5.3 years (SD 3.9)  
**Standard Care (n = 63)**  
Mean age of adolescent 13.1 years (SD 2)  
Mean age of parent 37.9 years (SD 5.9)  
Mean duration of diabetes 5.2 years (SD 4.8) | A1C adherence  
Metabolic control  
Hospital utilisation  
Twenty-Four Hour Recall Interview  
Frequency of blood glucose testing, a specific adherence behaviour, was also obtained directly from the adolescent’s blood glucose meter | 7 months | • Intent-to-treat analyses – significant improvements in the frequency of blood glucose testing in MST group  
• Number of inpatient admissions decreased in MST group, and increased in control group  
• Per protocol analyses revealed a significant improvement in metabolic control for MST group compared with control group |
| 26.8 | Wysocki, Harris et al. (2000) USA | RCT examining the efficacy of Behavioral Family Systems Therapy (BFST) vs. education and support group (ES) vs. current therapy (CT) with 119 families of adolescents with diabetes | **BFST (n = 38)**  
Mean age 14.5 years (SD 1.2)  
39% male  
Mean duration of IDDM 5.4 years (SD 3.8)  
**ES (n = 40)**  
Mean age 14.1 years (SD 1.4)  
38% male  
Mean duration of IDDM 4.5 years (SD 3.7)  
**CT (n = 41)**  
Mean age 14.3 years (SD 1.4)  
49% male  
Mean duration of IDDM 5.2 years (SD 3.8) | Demographic factors  
Parent-adolescent relationships – Parent-Adolescent Relationship Questionnaire, Issues Checklist, Conflict Behavior Questionnaire  
IDDM-Specific Psychological Adjustment – Teen Adjustment to Diabetes Scale, Diabetes Responsibility and Conflict Scale  
IDDM Treatment Adherence – Self-Care Inventory  
Health status – blood sample for glyced haemoglobin assays to index recent diabetic control | 3 months (end of treatment, reported in this study) 6 months 12 months | • BFST was more effective in improving parent-adolescent relationships and reducing diabetes-specific conflict, compared to CT and ES  
• N effects on treatment adherence  
• Some improvement in parent-adolescent relationships in BFST group – effects on diabetes outcomes depended on the adolescent’s age and gender |
| 26.9 | Viner, Christie et al. (2003) UK | Non-randomised controlled study examining effects of a motivational and solution-focused therapy group intervention in adolescents with poorly controlled diabetes | **Intervention (n = 21)**  
Mean age 13.0 years  
72% female  
**Control (n = 20)**  
Mean age 13.3 years  
40% female | Glycaemic control – HbA1C | 4-6 months 7-12 months | • Significant improvement of 1.5% in HbA1c in intervention group at 4–6 months post intervention compared with no change in controls  
• Improvement was partly maintained at 7–12 months post-intervention |
| 26.10 | Harris, Freeman et al. (2009) USA | Before-after comparison study evaluating the effectiveness of home-based Behavioral Family Systems Therapy (BFST) on improvements in parent–adolescent conflict in adolescents with poorly controlled diabetes. | BFST group (n=18) Mean age 16 years (SD 0.9) 33% femaleComparison group (n = 40) Mean age 15.2 (SD 1.5) 55% females| Diabetes Responsibility and Conflict Scale (DRC) Conflict Behavior Questionnaire (CBQ) HBa1c testOutcomes: Parent-adolescent conflict | Post treatment | • Home-based BFST is effective in reducing diabetes–specific conflicts between adolescents and their parents. • BFST is also effective in reducing parent-reported general conflicts between young people and their parents. • Correlations between HBa1c levels and measures of family conflict at pre and post treatment were non-significant. |

<p>| 26.12 | Wysocki, Harris et al. (2008) USA | RCT study evaluating Behavioral Family SYSTEMS Therapy for Diabetes (BFST-D) vs. 6 months of an educational support group (ES) vs. Standard Care (SC) for families of adolescents experiencing problematic management of Type 1 diabetes. | 104 adolescents 102 mothers 87 fathersBFST-D (n = 36) Mean age 13.9 years (SD 1.9) 58% maleES (n=36) Mean age 14.4 years (SD 1.9) 56% maleSC (n = 32) Mean age 14.2±1.9 50% male | Glycosylated hemoglobin (HbA1C) Diabetes Responsibility and Conflict Scale(DRC) Diabetes Self Management Profile (DSMP) Family problem-solving discussions (Interaction Behavior Code) Outcomes: Changes in family communication | 12 months 18 months | • BFST-D groups showed significantly improvement family interaction compared to SC and ES. • BFST-D had a positive effect on individual communication. Adolescents and their mothers in BFST-D groups demonstrated significantly reduction in negative communication from pre tests (3.5, 3.8) to 6 month post tests (2.1, 2.5) respectively when compared to ES and SC groups. However, there were no statistically significant effects for fathers. • Study reports possible link between changes in family communication, changes in glycemic control and treatment adherence. |</p>

</tbody>
</table>
|      | • Compared to hospitalisation, MST was more effective in decreasing youth externalizing symptoms, improving family cohesion and adaptability, increasing school attendance, and promoting consumer satisfaction
|      | • The reduction in use and length of hospitalization was not offset by increased use of other placement options, as MST reduced days in other out-of-home placements by 49% |
| 28.8 | Nickel, Muehlbacher et al. (2006) | 
|      | Germany                   |
|      | RCT evaluating the efficacy of a 12-week brief strategic family therapy (BSFT) vs. control group (no treatment) on outcomes in adolescent boys with bullying behaviour |
|      | All boys aged between 14-15 years, 100% male |
|      | BSFT (n = 36)              |

|      | Control group; n =20      |
|      | Adolescents' Risk-taking Behavior Scale (ARBS) |
|      | State-Trait Anger Expression Inventory (STAXI) |
|      | Inventory of Interpersonal Problems (MP-D) |
|      | SF-36 Health Survey (SF-36) |
|      | 12 months                 |
|      | • Intent to treat analyses indicated a significant reduction in bullying behaviour in the BSFT, compared to the control group
|      | • Also, statistically significant changes in all risk-taking behaviours (ARBS), on most STAXI, MP-D, and SF-36 scales were seen for BSFT group
|      | • Reduction in expressive aggression (Anger-Out scale of the STAXI) correlated with the reduction on several scales of the ARBS, IIP-D, and SF-36
|      | • Positive results maintained at follow-up |
| 28.10 | Timmons-Mitchell, Bender et al. (2006) USA | RCT evaluating the efficacy of multisystemic treatment (MST) vs. treatment as usual (TAU) in the treatment of 93 juvenile adolescents who had appeared before a family court | MST; $n = 48$ TAU; $n = 45$ Mean age 15.1 years (SD 1.25) | Recidivism Child functioning - Child and Adolescent Functional Assessment Scale | 6 months 12 months 18 months | • The hypotheses, that MST would be superior to treatment as usual in (a) reducing rearrest and (b) improving functioning during the time of treatment and at follow-up were partially supported  
• Specifically, MST resulted in decreased recidivism compared with the effects of usual court services |
| 28.11 | Nickel, Krawczyk et al. (2005) Germany | RCT evaluating the efficacy of a 6-month family therapy program vs. placebo intervention program for bullying behaviour in boys | All boys aged between 14-16 years, 100% male  
FT ($n = 22$)  
Placebo ($n = 22$) | Adolescents Risky-Behavior Scale (ARBS), the State-Trait Anger Expression Inventory (STAXI), the Inventory of Interpersonal Problems (IIP-D), and the SF-36 Health Survey (SF-36) | 12 months after treatment | • Reduction in bullying behaviour in family therapy group compared to control group  
• At 6-month follow-up, significant changes on all ARBS scales and on the STAXI scales State-Anger, Trait-Anger, Anger-Out, and Anger-Control for family therapy group  
• Significant differences on the following IIP-D scales: overly autocratic, overly competitive, overly introverted, overly expressive, and exploitable/compliant  
• Significant differences on the following SF-36 scales: general health perceptions, vitality, social functioning, role-emotional, and mental health  
• The reduction in expression of anger correlated with a reduction in several scales of the ARBS, IIP-D, and SF-36.  
• Treatment effects maintained at 1-year follow-up |
| 28.12 | Nickel, Nickel et al. (2005) Germany | RCT evaluating the efficacy of family psychotherapy (FT) vs. control group (no treatment) in treating anger and aggression in females aged 14-16 years | FT ($n = 13$)  
Control Group ($n = 12$) | Aggression and change in aggression were measured using the State-Trait Anger Expression Inventory (STAXI). | 6 months post-treatment | Significant changes on all five scales of STAXI for FT group compared to control group |
| 28.13 | Rowland, Halliday-Boykins et al. (2005) USA | RCT examining the effectiveness of multisystemic therapy (MST) vs. usual services in 31 adolescents with serious emotional disturbance | MST; $n = 15$ Usual services; $n = 16$ Mean age 14.5 years 58% male | Child Behaviour Checklist Youth Risk Behavior Survey Substance use - Personal Experience Inventory Criminal activity – Self-Report Delinquency Scale School placement | 6 months | • Compared to usual services, MST condition reported significant reductions in externalizing symptoms, internalizing symptoms, and minor criminal activity; their caregivers reported near significant increases in social support; and archival records showed that MST youths experienced significantly fewer days in out-of-home placement |
| 28.14 | Brotman, Dawson-McClure et al. (2005) USA | RCT assessing the efficacy of a family-based preventive intervention for conduct problems in pre-school age siblings of adjudicated adolescents | 47 families recruited Intervention; $n = 26$ Control; $n = 21$ Main outcomes: children’s antisocial behaviour and peer relations New York Parent Rating Scale New York Teacher | Post-intervention 8 months | • At eight-month follow-up, significant effects for adolescent siblings on parent-reported antisocial behaviour and positive peer relations  
• Teacher reports confirmed group differences for antisocial behaviour immediately after intervention |

<td>RCT pilot study examining the initial efficacy of the Parent-Child Interaction Therapy (PCIT) vs a 3.5-month waiting-list condition for children with diagnosed attention</td>
<td>32 preschool children and their families recruited, all children had a diagnosis of ADHD (combined or disruptive type)</td>
<td>Disruptive Behavior Scale for Children-Spanish Hyperactivity and Aggression Subscales of the Behavioral</td>
<td>3.5 months</td>
<td>• Significant differences between PCIT and WL conditions at post treatment evaluation. • PCIT group reported significant reduction in children’s hyperactivity-impulsivity, inattention, and oppositional defiant and aggressive behaviour problems</td>
<td></td>
</tr>
</tbody>
</table>
deficit/hyperactivity disorder (ADHD) and conduct behaviour problems.

**PCIT intervention** *(n = 20)*
- Age range 4-6 years old
- 19 families completed measures
- 17 families completed the follow-up assessment

**Control Group (n = 12)**
- Age range 4-6 years old

**Assessment System for Children-Parent Rating Scale (BASC-PRS-Spanish)**
- The Peabody Picture Vocabulary Test (Hispanic American Adaptation) (PPVT-HAA)
- NIMH Diagnostic Interview Schedule for Children IV Parent Version
- Children’s Global Assessment Scale Spanish
- Eyberg Child Behavior Inventory
- Family Experiences Inventory
- Parent Practices Inventory
- Beck Depression Inventory Spanish
- Treatment Evaluation Scale
- Therapy Attitude Inventory

- Reported large treatment effect sizes *(1.37–2.04)* indicating significant behaviour changes
- The mean percent of treated children with clinically significant changes was 62.5 at post treatment and 55 at follow-up
- Treatment gains of PCIT intervention were clinically significant and were maintained at the 3.5-month follow-up.
